

**COMPARATIVE STUDY OF DEMOGRAPHIC PROFILE
OF CANCER CERVIX PATIENTS ATTENDING IOG
IN THE CURRENT PERIOD WITH THAT
OF FIVE YEARS AGO**

Dissertation submitted to

THE TAMILNADU Dr. M.G.R. MEDICAL UNIVERSITY

In partial fulfilment for the award of the Degree of

M.S. (OBSTETRICS AND GYNAECOLOGY)

BRANCH II

MADRAS MEDICAL COLLEGE

CHENNAI

APRIL 2017

BONAFIDE CERTIFICATE

This is to certify that the dissertation titled **“COMPARATIVE STUDY OF DEMOGRAPHIC PROFILE OF CANCER CERVIX PATIENTS ATTENDING IOG IN THE CURRENT PERIOD WITH THAT OF FIVE YEARS AGO”** is the bonafide work done by Dr D. Kavitha during her M.S. (OG) course at Madras Medical College, Chennai.

Prof. Dr. Sarala, MD., DGO.,
Professor,
Institute of Obstetrics and Gynaecology,
Govt. Women and Children Hospital,
Madras Medical College,
Chennai – 600 005.

Prof.Dr.S.Baby Vasumathi. MD.,DGO.,
Director and Superintendent
Institute of Obstetrics and Gynaecology,
Govt. Women and Children Hospital,
Madras Medical College,
Chennai – 600 005.

Dr.M.K. Muralidharan, MS., MCH.,
Dean
Madras Medical College,
Chennai- 600 003

DECLARATION

I, Dr. D. Kavitha, solemnly declare that the dissertation titled, **“COMPARATIVE STUDY OF DEMOGRAPHIC PROFILE OF CANCER CERVIX PATIENTS ATTENDING IOG IN THE CURRENT PERIOD WITH THAT OF FIVE YEARS AGO”** has been done by me. I also declare that this bonafide work or part of this work was not submitted by me for any award, degree, diploma to any other university either in India or abroad. This is submitted to The Tamil Nadu Dr.MGR medical University, Chennai in partial fulfillment of the rules and regulations for the award of M.S Degree (Obstetrics and Gynaecology) held in April 2017.

Place:

Date:

Dr. D. KAVITHA

ACKNOWLEDGEMENT

I would like to thank **Prof. Dr. K. MURALIDHARAN M.S., M.Ch,** **Dean,** Madras Medical College for having permitted me to do this dissertation work.

It is my pleasure to express my thanks to **Prof. Dr. BABY VASUMATHY M.D., D.G.O.,** Director, Institute of Obstetrics & Gynaecology, Egmore for her valuable guidance, interest and encouragement in this study.

I take this opportunity to express my deep sense of gratitude and humble regards to my beloved teacher and guide Dr. Sarala M.D., D.G.O., for her timely guidance, suggestion and constant inspiration which enabled me to complete this dissertation.

I thank all my Professors, Asst Professors and paramedical staff of this Institute.

I thank my family and friends for their inspiration and support given to me. I thank Mr. Padmanabhan Statistician who helped me for statistical analysis.

Introduction

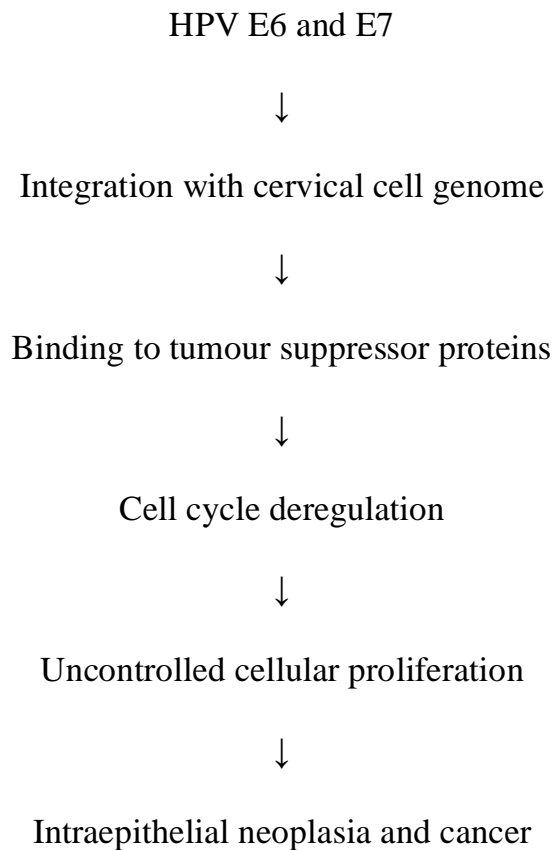

INTRODUCTION

Cervical Cancer is an important cause of morbidity and mortality in women worldwide. In developing countries where healthcare resources are limited, the second frequent cause of cancer death in women is cancer cervix.

With appropriate diagnosis, treatment and follow-up, Cervical Cancer can be prevented and cured at low cost with the available screening for asymptomatic women.

The age distribution of the patients is bimodal with high incidence at 35 to 39 years and 60 to 64 years of age.

Carcinoma of the cervix is a multifactorial disease and main causative agent is Human Papilloma Virus. It is determined to be the main agent in the development of squamous and adenocarcinoma of the cervix. Of the 14 high risk HPV subtypes: 16 & 18 are found in 62 % of cervical cancer. The mechanism is through the interaction of the viral E6 and E7 proteins with tumour suppressor genes p53 and Rb. Inhibition of p53 prevents cell cycle arrests and cellular apoptosis, inhibition of Rb disrupts transcription factor E2f resulting in unrepleted cellular proliferation.

However epidemiological studies have analysed many other risk factors like younger age at first intercourse (less than 16 years), multiple sexual partners, race, increased parity, environmental factors, genetic predisposition, cigarette smoking, low socioeconomic status and chronic immune suppression, micronutrient deficiency and others.

Therefore socio-demographic risk quantification of cancer cervix has taken prime importance in evolution of programmes in public health for cancer cervix control.

Aim of Study

AIM OF THE STUDY

This study compares the socio-demographic profile of patients with carcinoma cervix attending IOG in the current period 2014-15 with that of 5 years ago i.e.2009-10

Review of Literature

REVIEW OF LITERATURE

Among the risk factors human papilloma virus is an important etiological agent. It is a circular double stranded DNA virus which causes sexually transmitted infection. HPV can replicate only in stratified squamous epithelium. There are nearly about 150 related viruses in this HPV group, 6 and 11 cause papilloma which are known as warts. HPV 16, 18, 31, 33, 45 are high risk types because they cause cancers of cervix, vagina, vulva in women & cancer of the penis in men.

HPV affects cellular differentiation and growth through interaction of viral E6, E7 protein with tumour suppressor genes p53 and Rb respectively. Cell cycle arrest and cellular apoptosis is caused by p53 inhibition, which normally occurs when damaged DNA is present, while inhibition of Rb disrupts transcription factor E2F and causes unregulated cellular proliferation.

Other risk factors are women of young age at first intercourse and younger age at first term pregnancy. Women who are less than 16 years and who had their first term pregnancy at younger age are at two folds increased risk to develop cervical cancer at a later stage.

Multiple sexual partners, partners having multiple sexual partners, smoking, immunocompromised individuals due to conditions like HIV or due to certain medications such as immunosuppressants, those who are on oral contraceptive pills for more than 5yrs, high parity, low socioeconomic status are other risk factors.

SCREENING FOR CERVICAL CANCER

Secondary prevention involves screening of precancerous lesions and treating them. The various screening modalities includes Cytology, visual inspection and HPV DNA test.

The squamocolumnar junction(SCJ) is the junction between the squamous epithelium and columnar epithelium and its location on cervix is variable. This is due to continuous remodelling process due to uterine growth, hormonal status, and cervical enlargement. SCJ is situated at or very nearer to external Os at birth and in premenarchal years. SCJ is located at variable distance from the external os during reproductive age. In the postmenopausal women the new SCJ is not seen as it has receded into the endocervix.

PAPSMEAR

Pap test which is an abbreviation of Papanicolaou test is a cervical screening method to detect precancerous and cancerous processes in the cervix. The Greek doctor Georgios Papanicolaou invented this test. A speculum is used to visualize the cervix and cells from squamo columnar junction are scraped and fixed on glass slide in cytology .The cells which are collected are examined under microscope to check for abnormalities.

This pap smear has increased false negative rates, subjective interpretation, low predictive and low sensitivity value since one third had a normal pap smear but still developed cancer cervix.

Cells from the cervix are scraped with spatula and examined under microscope

VISUAL INSPECTION METHODS:

SCHILLER IN 1930 applied lugol's iodine and inspected the cervix. This Schiller's test was the first method and has poor specificity. This visual inspection is a screening tool for low resource settings and it is economic and the results are immediate. Visual inspection is done with acetic acid (VIA) and Lugol's iodine (VILI). The idea behind Visual screening is that a high concentration of intracellular proteins will lead to dense acetowhitening effect. It requires minimum equipment, inexpensive

and easy to learn. In women who do not have access to cervical cytology and HPV testing have to undergo visual inspection. If thick bright mustard yellow or saffron yellow iodine non uptake areas are visualized in the transformation zone nearer the os or abutting the squamo columnar junction or if squamo columnar junction is not seen or when the cervix becomes yellow fully invasive cancer is suspected..Invasive carcinoma is also reported, when on application of iodine on the cervix ,a nodular frank irregular ulceroproliferative growth appears which becomes densely yellow.

- **VILI: Positive which is indicated by well defined by canary yellow and transformation zone**
- **Vili negative indicated by Mahogany brown**

The sensitivity of VIA in the detection of CIN2 and CIN3 lesions and invasive cervical cancer is from 49% to 96% and specificity from 49% to 98%. The sensitivity and specificity in visual inspection with lugol's iodine in detection of high grade CIN were 92% and 85% versus 77% and 86% for VIA. Therefore there is high sensitivity for VILI, but the specificity for VILI and VIA are similar.

HPV DNA testing sensitivity varies from 45.7% to 80.9% for detecting CIN grade 2 or worse. This test is expensive and requires infrastructure with sophisticated labs.

COLPOSCOPY

Colposcopy is a diagnostic procedure to examine magnified illuminated view of the cervix and tissues of vulva and vagina. Colposcopy should be done in all suspected early invasive cancer patients based on cervical cytology and in grossly normal appearing cervix .

The features suggesting invasion include abnormal blood vessels, contour of the surface being irregular with loss of surface epithelium, change in the colour tone. Biopsy is also taken under colposcopic guidance. Colposcopy directed biopsy makes the diagnosis of frank invasion and avoids cone biopsy and hence treatment can be started without delay. Patients with abnormal pap smear cytology must undergo colposcopic examination. In patients who are CIN2 and CIN3 positive and with adequate colposcopic examination both ablation and excision are acceptable treatment modalities. High grade and low grade differentiation is better performed with colposcopy and it is the gold standard for diagnosis of

cervical cancer. Hence pap smear, colposcopy and histopathology should be collectively used in cancer cervix patients.

Sreedevi A, et al ¹ (2015) attempted to review the knowledge available regarding pattern and epidemiology of cervical cancer, various types of HPV prevalence among cancer cervix patients ,various groups which are at increased risk such as HIV positive women, commercial sex workers. The study reviewed that 55 to 59 years is the peak age of incidence and considerable number of women reported in late stage of disease. HPV 16,18 have been detected in patients with cervical cancer.

Young age at marriage, multiple sex partners, high parity, poor hygiene, malnutrition, use of oral contraceptive pills are some of the other risk factors.. A multipronged approach is a must that targets on high prevalent areas and routine early screening with VIA. Vaccine against HPV 16and 18 should also be under taken to prevent cancer cervix ..

There is a national programme for cancer since 1975 which gave importance to equip premier cancer institution,that by 1984 to 1985 was shifted to early detection and primary prevention of cases,by 1990 to 1991 to cancer control programme in district.

In 2008 recognition and creation of new regional centers, strengthening of the regional centers, creating wings in oncology in medical college hospitals, cancer control programme in the district, decentralised NGO schemes were the main priorities in programme 6.

Cancer control became more comprehensive large programme on non-communicable disease called NPCDCS (National Programme For Prevention And Control Of Cancer, Diabetes, Cardiovascular Diseases, Stroke) in 2010, in which common risk factors are being addressed in an integrated manner. The present programme emphasis reduction in the risk, promoted screening of the patients through camps in women over 30yrs at various levels in rural areas and urban slum. It also promotes comprehensive cancer care at the level of district hospitals and also at tertiary care centres.

An analysis made on population based surveys showed that coverage of screening for cancer cervix in developing countries is 19% when compared to 63% in developed countries and ranges from 1% in Bangladesh to 73% in Brazil.

Opportunistic screening done in different parts of India were from 6.9% in Kerala to 0.006% , 0.002% in western state of Maharashtra and South Tamilnadu respectively. Most cases presented in late stages and more

than 50% at the time of presentation had regional disease. Diagnosis made in late stages had a poor prognosis resulting in poor compliance. The present carcinogenesis include three steps of HPV infection, progress to high grade preinvasive lesion and invasion. The sensitivity is 25% in HPV testing but specificity is 10% lower ,combination of cytology and HPV test gives a negative predictive value of 100%.

A study made in a tertiary care centre in the eastern parts of India showed that 38.8% had completed treatment with external radiation and brachytherapy. Elderly women, having many children at home and difficult to travel were the reasons mentioned. For thousands of poor women post diagnosis scenario is also bleak.

Anderson GH et al² (1992) studied 437 patient's charts who were newly diagnosed to have invasive cancer cervix seen in British Columbia during 1985to1988 .They were reviewed to detect the age at diagnosis ,stages of the disease, histology of lesions. They found 55% were of age 50 or over and 34% had stage 1 preclinical disease.39% had never cytological examination and 45 additional patients did not have cytology for five or more years before presenting with invasive disease.49% were in category of "no cytology or cytology longer than five years ago". In 15% having previous cytology, abnormal cells had been missed.10% cases of invasive carcinoma were made up by native Indian women. They concluded that if

reduction of death rates from invasive carcinoma cervix is needed, new means must be found to encourage women to participate in pap smear screening programme.

Sreejata Raychaudri et al³ (2012) performed a comparative analysis of behavioural risk factors of cancer cervix and sociodemographic knowledge and attitude and practice between urban and rural women of North Bengal, India. A survey had been conducted in rural areas among 133 women (Kawakhali) and in an urban slum (Shakthgargh) among 288 women using semi structured questionnaires .The study concluded that numerous risk factors were found in both areas ,but rural areas had high prevalence. The role of education and level of awareness seems to be insignificant determinants in rural areas when compared to urban areas .This study necessitates to be closely followed up by large scale programme to reorient campaign regarding awareness in rural areas .

Lyimo FS et al⁴ In Tanzania, the rate of incidence is 30 to 40 per 10000 women, showing the disease burden to be high.. Screening for cancer cervix is the most effective approach currently for control of cancer cervix and are associated with reduced incidence of mortality. A cross sectional study was conducted in three hundred and fifty four women between eighteen to sixty nine years living in Moshi renal district. One hour interview was conducted at the home of each woman. The results were

less than one quarter(22.6%) has screening for cancer cervix. The following characteristics were significant that is approval from husband for screening of cancer cervix, level of education ,the knowledge and its prevention ,concern about the pain of screening, awareness of women regarding the distance to screening services. They concluded that 3 recommendations were made. First, information regarding cervical cancer must be given to women; Second, public information regarding how to prevent as well as screening services; Third ,providing cancer cervix screening services within 5km from the women's residence.

Study by Naomi Brewer at Massey University ⁵ In this thesis he describes a series of the stage at diagnosis and subsequent survival of women registered with cancer cervix in New Zealand and the various factors that will contribute to the demographic differences which were found in both stages at diagnosis and survival. All the registered cancer cervix cases were involved in the study.

Foley G et al ⁶In this analysis information on 71511 incident cases of cancer cervix in England was extracted from database. The incidence cases were analysed by age group, birth cohort and time period. Annual percentage change was estimated by Poisson regression. Birth cohorts who were called for screening between 60 to 64 years and 35 to 39 years showed a peak incidence soon after the age of presumed first screen while younger

birth cohorts showed a peak incidence at 35 years. They concluded that the results had implications for cervical screening, HPV vaccination and other intervention on public health which targeted young women.

Materials & Methods

MATERIALS AND METHODS

It is a retrospective case control study conducted at Institute of Obstetrics & Gynaecology Egmore, Chennai 8. The duration of study was one year and six months

METHODOLOGY:

This is a record based comparative and descriptive study conducted in IOG. The data source is from IOG audit. The sociodemographic profile of carcinoma cervix patients who were treated in IOG in the current study period 2014-2015 will be compared with that of 5 years ago 2009-2010. The detailed history will be recorded in the proforma.

INCLUSION CRITERIA:

- All patients with cancer cervix with histopathological confirmation who were treated in IOG in 2009-2010 and 2014-2015.

EXCLUSION CRITERIS:

- Patients whose available records are incomplete
- Patients without histopathological confirmation

PROCEDURE:

Records of all cancer cervix patients admitted in IOG in the years 2009, 2010, 2014 & 2015 were obtained from Medical Records Section, IOG and analysed.

DATA COLLECTION & METHODS:

- The following data was collected - Age, residential area, religion, educational status, occupation, socio-economic status, marital status, age at marriage, parity, age at first issue, referral, screening method which first detected, Colposcopy confirmation, presenting symptoms, type of lesion, stage of disease, biopsy findings are collected from IOG audit and statistical analysis done.

Results & Analysis

RESULTS AND ANALYSIS

The study analysed the outcome using various parameters. The results were subjected to statistical analysis using T test and Chi-square test

Age * group

Crosstab				
Age		Group		Total
		2009-2010	2014-2015	
<35 YRS	Count	13	28	41
	% within group	3.3%	3.9%	3.7%
35-40 YRS	Count	52	75	127
	% within group	13.3%	10.5%	11.5%
41-45 YRS	Count	55	106	161
	% within group	14.0%	14.9%	14.6%
46-50 YRS	Count	61	125	186
	% within group	15.6%	17.6%	16.9%
> 50 YRS	Count	211	377	588
	% within group	53.8%	53.0%	53.3%
Total	Count	392	711	1103
	% within group	100.0%	100.0%	100.0%

Chi-Square Tests			
	Value	Df	Asymp. Sig. (2-sided)
Pearson Chi-Square	2.658 ^a	4	.617
Likelihood Ratio	2.638	4	.620
Linear-by-Linear Association	.061	1	.805
N of Valid Cases	1103		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 14.57.			

The number of cancer cervix detected patients increased was 81% in the current period when compared to previous period. Interesting factor is that the detection in less than 35 years of age in 2009-2010 period is 31.7% whereas in 2014-2015 it is 68.3%. This shows the early detection of cases in the current period has increased. Subsequently the detection in other age groups is also increasing than the previous period. Eventhough age distribution between two periods is not statistically significant as evidenced by chi square value of 2.658 and p value of 0.617, the distribution of number of cases between two periods is uniformly increasing and this shows the number of detected cases between two periods. We can see elevation in cancer cervix detected cases.

Residence * group

Crosstab				
Residence		Group		Total
		2009-2010	2014-2015	
RURAL	Count	211	535	746
	% within group	53.8%	75.2%	67.6%
URBAN	Count	181	176	357
	% within group	46.2%	24.8%	32.4%
Total	Count	392	711	1103
	% within group	100.0%	100.0%	100.0%

Chi-Square Tests					
	Value	Df	Asymp. Sig. (2-sided)	Exact Sig. (2-sided)	Exact Sig. (1-sided)
Pearson Chi-Square	52.960 ^a	1	.000		
Continuity Correction ^b	51.986	1	.000		
Likelihood Ratio	51.995	1	.000		
Fisher's Exact Test				.000	.000
Linear-by-Linear Association	52.912	1	.000		
N of Valid Cases	1103				
<p>a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 126.88.</p> <p>b. b. Computed only for a 2x2 table</p>					

There exists a statistical significance between two periods with respect to residence as evidenced by chi square value of 52.960 and p value of 0.000. This is mainly due to awareness created by various Government programmes, and advertisements by media persons among rural folks. This is evidenced from the above table where 75.2% detected cases in 2014-2015 than previous period 2009-2010 of 53.8%. This clearly shows cancer detection is more in rural areas.

Religion * group

Crosstab				
Religion		Group		Total
		2009-2010	2014-2015	
HINDU	Count	381	700	1081
	% within group	97.2%	98.5%	98.0%
MUSLIM	Count	5	4	9
	% within group	1.3%	.6%	.8%
CHRISTIAN	Count	6	7	13
	% within group	1.5%	1.0%	1.2%
Total	Count	392	711	1103
	% within group	100.0%	100.0%	100.0%

Chi-Square Tests			
	Value	Df	Asymp. Sig. (2-sided)
Pearson Chi-Square	2.254 ^a	2	.324
Likelihood Ratio	2.151	2	.341
Linear-by-Linear Association	1.515	1	.218
N of Valid Cases	1103		
a. 2 cells (33.3%) have expected count less than 5. The minimum expected count is 3.20.			

There is no statistical significance between different religions with respect to the two periods which is evidenced by chi square value of 2.254 and p value of 0.324. Majority of the population were Hindus while Christians and Muslims were least. The table reveals that the detection of Cancer cervix among Christian and Muslim population is not increasing like Hindu population in both periods.

Education * group

Crosstab				
Education		Group		Total
		2009-2010	2014-2015	
ILLITERATE	Count	91	40	131
	% within group	23.2%	5.6%	11.9%
PRIMARY	Count	278	639	917
	% within group	70.9%	89.9%	83.1%
SECONDARY	Count	23	32	55
	% within group	5.9%	4.5%	5.0%
Total	Count	392	711	1103
	% within group	100.0%	100.0%	100.0%

Chi-Square Tests			
	Value	Df	Asymp. Sig. (2-sided)
Pearson Chi-Square	77.684 ^a	2	.000
Likelihood Ratio	74.315	2	.000
Linear-by-Linear Association	40.537	1	.000
N of Valid Cases	1103		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 19.55.			

There exist a statistical significance among two groups with respect to education as evidenced by chi square value of 77.684 and p value of 0.000 between two periods.

Illiterate population in the present period has been reduced when compared five years ago as per educational statistics. We also infer that cancer detected cases were prevalent more in the literate group and also among rural population by the awareness program by health providers in the current period.

Occupation * group

Crosstab				
Occupation		Group		Total
		2009-2010	2014-2015	
NOT WORKING	Count	311	561	872
	% within group	79.3%	78.9%	79.1%

	% within group	100.0%	100.0%	100.0%

Chi-Square Tests					
	Value	Df	Asymp. Sig. (2-sided)	Exact Sig. (2-sided)	Exact Sig. (1-sided)
Pearson Chi-Square	.180 ^a	1	.671		
Continuity Correction ^b	.109	1	.742		
Likelihood Ratio	.179	1	.672		
Fisher's Exact Test				.706	.369
Linear-by-Linear Association	.180	1	.672		
N of Valid Cases	1103				
<p>a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 49.76.</p> <p>b. Computed only for a 2x2 table</p>					

There is under reporting of cancer cervix patients from widowed/separated women in our study since these women never try to seek medical advice due to lack of financial, family, social support. Hence there is no statistical significance among two periods with respect to Marital Status as evidenced by chi square of 0.180 and p value of 0.671.

Age at marriage (years) * group

Crosstab				
Age of marriage (years)		Group		
		2009-2010	2014-2015	Total
<16 YEARS	Count	160	8	168
	% within group	40.8%	1.1%	15.2%
16-18 YEARS	Count	199	172	371
	% within group	50.8%	24.2%	33.6%
19-21 YEARS	Count	33	299	332
	% within group	8.4%	42.1%	30.1%
> 21 YEARS	Count	0	232	232
	% within group	.0%	32.6%	21.0%
Total	Count	392	711	1103
	% within group	100.0%	100.0%	100.0%

Chi-Square Tests			
	Value	Df	Asymp. Sig. (2-sided)
Pearson Chi-Square	537.292 ^a	3	.000
Likelihood Ratio	643.845	3	.000
Linear-by-Linear Association	499.619	1	.000
N of Valid Cases	1103		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 59.71.			

There exists a statistical significance between two periods with respect to age of marriage as evidenced by chi square value of 537.292 and p value of 0.000. The table inferred that there is steep decrease of early marriages in the current period when compared to previous period. As literacy rate and awareness of child marriage problems are increasing , early onset of marriage has been reduced in the current period.

Parity status

Crosstab				
Parity status		Group		
		2009-2010	2014-2015	Total

Chi-Square Tests					
	Value	Df	Asymp. Sig. (2-sided)	Exact Sig. (2-sided)	Exact Sig. (1-sided)
Pearson Chi-Square	75.323 ^a	1	.000		
Continuity Correction ^b	73.769	1	.000		
Likelihood Ratio	71.932	1	.000		
Fisher's Exact Test				.000	.000
Linear-by-Linear Association	75.255	1	.000		
N of Valid Cases	1103				
<p>a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 55.80.</p> <p>b. Computed only for a 2x2 table</p>					

There exists a statistical significance among two periods with respect to parity status as evidenced by chi square value of 75.323 and p value of 0.000. Here in the present period parity upto 5 are 92.5% than previous period of 73%. This clearly shows cancer cervix detection is elevated in high parity women.

Age at Ist issue * group

There exists a statistical significance between the two periods with respect to moderately differentiated squamous cell carcinoma and poorly differentiated squamous cell carcinoma as evidenced by chi square value of 245.339 and p value of 0.000. Moderately differentiated Carcinoma were 68.2% in 2014-2015 compared to previous period of 19.1% in 2009-2010. Poorly differentiated carcinoma has been reduced to 29.3% when compared to previous period of 71.7% .

Discussion

DISCUSSION

This study compares the socio-demographic profile of cancer cervix patients attending IOG in the current period 2014-2015 with that of five years ago 2009-2010.

The pre-cancerous period of cancer cervix is generally 10 to 15 years. Hence it provides considerable window of opportunities to detect and treat it completely. In the routine checkup of all women if regular screening is made a part, then the onset of cancer can be detected and combated effectively.

HPV is the main causative agent of cancer cervix. HPV falls into two groups

1. Low risk HPV-HPV types 6,11 cause genital warts and do not cause cancer. It causes only skin warts (condylomata accuminata) in and around the genital areas, anus and throat and mouth.
2. High risk HPV-There are many high risk HPVs but 16 and 18 are main causative agent for most HPV caused cancers.

Additional risk factors include

Early age at first intercourse, Young age at term pregnancy, Multiple sexual partner, Partners having multiple sexual partners, Smoking which causes increased likelihood of persistence of HPV in the body, Immuno compromised women –those women who are infected with HIV or AIDS, or those on medications which suppresses the immune system or organ transplant recipients are at increased risk of genital HPV infection, High parity, Low socio-economic status, Women on oral contraceptive pills for more than five year period are associated with a higher incidence of cancer cervix because the pills produce favourable environments for the virus.

Even though there is no statistical significance with respect to age between two periods as evidenced by chi square value of 2.658 and p value of 0.617, the distribution of number of cases between two periods are uniformly increasing . Interesting factor is that in women less than 35 years the detection in 2009-2010 is 31.7% whereas in 2014-2015 it is 68.3% showing the early detection in the current period.

In our study there is a statistical significance with respect to residence between two periods as evidenced by chi square value of 52.960 and p value of 0.000. Awareness campaigns and programmes are organized by the

Government which sensitises the entire community on all aspects of cancer cervix even among rural population . The risks factors of cancer cervix, the need for early detection and availability of free screening centres and services by the Government are the key messages of awareness campaigns. This is primary prevention. This is evidenced by the fact that the number of cases detected were 75.2% in 2014-2015 when compared to 53.8% in 2009-2010. The study of cancer incidents and education in rural population has shown that the risks are inversely proportional to increased levels of education. The reproductive factors, cancer detection, sexual behaviour, demographic and biological factors including nutrition, smoking are also influenced by education. Therefore there are sufficient evidence to say that role of education is vital. In our study there is statistical significance with respect to education between two periods as evidenced by chi square value of 77.684 and p value of 0.000. We infer that cancer detected cases were prevalent more in the present period.

There is no statistical significance between two periods with respect to religion as evidenced by chi square value of 2.254 and p value of 0.324. Economic status of the women were assessed by the occupation and family income.

In our study occupation or family income is not determining statistical significance among two periods as evidenced by chi square of 0.029 and p value of 0.865. There is no statistical significance with respect to socioeconomic status between two periods as evidenced by chi square value of 0.486 and p value of 0.784.

Sauvaget et al ⁷2011 A study made in rural West India showed that widows and women who are separated are at high risk of HPV infection. Specimens from cervix were taken and questionnaires regarding their lifestyle and their reproductive factors were given to 27,192 married women aged 30 to 59 years residing in Maharashtra State, India. The results were that 10.3% prevalence of HPV infection were among middle aged women. The conclusion of the study was low socio economic status and groups like widows and separated women are at higher risk.

Kaker et al ⁸2008 reported that there is an increased risk for diagnosis at late stage among widows and divorced women compared to women who are married. The reasons may be these women never try to seek medical advice due to lack of financial, family and social supports. In our study there is under reporting of cases mainly from widows and separated women in both periods and therefore it is statistically insignificant as evidenced by chi square value of 0.180 and p value of 0.671.

Biswas et al ⁹1997 there was a case control study conducted in a hospital in eastern part of Indian rural women which confirmed the close association between young age at first intercourse and incidence of cancer cervix.

Louie et al ¹⁰Age at marriage, age at first intercourse, age of the first pregnancy are all interrelated particularly in developing countries since there is a short latency period between age of marriage and age of first pregnancy. In this study a pooled analysis of case control study on cancer cervix from 8 countries were made and the risk for invasive carcinoma was 2.4 fold among women whose age at first intercourse and age at first pregnancy was early. The importance of vaccination for adolescents can have great influence on cancer cervix. In our study there exist a statistical significance with respect to age at marriage between two periods as evidenced by chi square value of 537.292 and p value of 0.000. There is a steep decrease of early marriages in the current period.

There exist a statistical significance with respect to age at first issue between two periods as evidenced by chi square value of 246.509 and p value of 0.000. There was no single case detected in the age less than 17 years in the present period when compared to 30.9% cases were detected in the previous period.

High parity is also a predominant factor for cancer cervix in our study.

In our study there exist a statistical significance with respect to high parity between two periods as evidenced by chi square value of 75.323 and p value of 0.000. Cancer detection was elevated in high parity women.

Varghese et al¹¹ (1999) The genital hygiene plays a major role in the development of cervical dysplasia and cancer which was studied in Kerala, India. Most women cannot afford sanitary napkins ,while facilities for washing after intercourse were not available for some .Illiteracy and poor hygiene, increased parity were found to be risk factors for cancer cervix.

Women with persistent infection with HPV is an important cause of progression to invasive carcinoma of the cervix. Assessment regarding HPV infection was not made and therefore cannot be considered in our analysis.

Smoking is rare in our population, but passive smoking or smoking history of women's husband were not taken because such information are not routinely collected in our analysis.

SCREENING

Screening is by per speculum examination ,pap smear ,VIA VILI and confirmation by colposcopic biopsy. Per speculum examination is having a sensitivity lesser compared with other methods. Pap smear is an easy cheap and quick method of screening .The pre requisite is to avoid putting anything in the vagina 24 to 48 hours before pap smear like having intercourse ,using tampons, applying vaginal creams.

In the current period only 5.8% patient were screened by Per speculum. Usually women are screened by Pap smear and VIA VILI and if test proves to be positive, they are referred for colposcopic evaluation and confirmation by biopsy and histopathological examination in the current period. Then grading of cancer cervix is done and treated accordingly.

Karimi et al¹² compared three methods of conventional pap smear LBC pap smear and colposcopy using z-test in the detection of cervical cancer .The results was that there was no significant relationship .In conclusion colposcopy has a higher sensitivity than pap smear and LBCpap smear.

Ashmita et al¹³ In this study the findings of pap smear ,colposcopy and histopathology were compared for detection of premalignant lesion of the cervix. They concluded that overall pap smear had a poor sensitivity when compared to colposcopy especially in low grade squamous intraepithelial lesions.Young age at intercourse and high parity are significant risk factor for cervical cancer.

Sukhpreet singh et al¹⁴ Compared the sensitivity ,specicity and predictive value of colposcopy and papanicolaou amear . All patients were subjected to Schiller's test and acetic white test before colposcopic directed biopsy .The number of CIN 1 and 2 patients detected by pap smear were 16% while colposcopic directed biopsy were accurate with 91.7 to 100%.

Malur et al ¹⁵ This study was a cross sectional study where 190 patients with postcoital bleeding ,postmenopausal bleeding and persistent vaginal discharge or those with unhealthy cervix were included .14.21% cases were Pap smear positive ,37.89 % were colposcopy positive. It concluded as sequential testing with pap smear and colposcopy increases accuracy in screening of cancer cervix.

Pap smear sensitivity is lesser due to the presence of infection and inflammation. In our analysis there exist a statistical significance with respect to screening method which first detected between two periods as evidenced by chi square of 282.834 and p value of 0.000.

Even though first initial screening of cancer cervix is only papsmear and VIA VILI during this current period, patients were also subjected to colposcopic confirmation. In our analysis there exist a statistical significance with respect to colposcopic confirmation between two periods as evidenced by chi square of 1103.000 and p value of 0.000. This clearly indicates that usage of colposcopy is a means of better detection by health authorities.

There is no statistical significance with respect to presenting symptoms between two periods as evidenced by chi square value of 0.634 and p value of 0.889. There is no statistical significance with respect to type of lesion between two periods as evidenced by chi square of 2.158 and p value of 0.340. Cancer cervix is detected at early stages in the present period which is 11.2% when compared to the previous period of 6%. Hence in our study there is statistical significance with respect to stages of the disease between two periods as evidenced by chi square value of 34.271 and p value of 0.000. As the socio economic profile improved with increased literacy

rates and better awareness created by various government programmes and campaigns even in rural areas in the current period , and with the different screening strategies the detection of cancer cervix is done in the early stages itself and the treatment started early ,thereby reducing the mortality in India.

The best way to protect women against cancer cervix is to have vaccine, and regular screening. HPV vaccine can be given to girls between 11 and 12 years. But girls and women of age 13 to 26 can also be vaccinated. Ideally women should be vaccinated before they become sexually active and exposed to HPV. But women who are sexually active may also be benefited from vaccination, but their benefits are less. This is because they may be exposed already to one or more types of HPV .

Vaccines are given in three shots over six months. Vaccination is not recommended for pregnant women. Girls need not be screened with HPV test or Pap test to find out if they should get the vaccine. These vaccines target HPV types that most commonly cause cancer cervix. The vaccinated individuals are protected for ten years. The Food And Drug Administration has approved 3 vaccines –Gardasil, Gardasil 9, and Cervarix. They are effective against new HPV infections but ineffective in already established HPV infections.

Gardasil is a quadrivalent vaccine since it is effective against HPV 16,18,6,11.

Gardasil-9 protects against 9 HPV types and therefore it is a nonavalent vaccine. Cervarix vaccine is a bivalent vaccine as it targets HPV types 16 and 18 .HPV vaccine stimulate the body to produce antibody which binds to the virus and prevents it from infecting the cells. These vaccines are virus like particles and are found by HPV surface components. These virus like particles are highly immunogenic that means they stimulate high levels of antibody production which also makes the vaccines more effective.

Summary

SUMMARY

This is a comparative study of the socio demographic profile of cancer cervix patients attending IOG in the current period with that of five years ago

In this study, the number of cancer cervix detected patients increased to 81% in the current period when compared to the previous period. In the age group of less than 35 years in 2009-2010 the detection is 31.7% whereas in 2014-2015 it is 68.3%. This shows early detection of cases in the present period. Subsequently the detection in other age group is also increasing than the previous period. Even though age distribution between two periods are not statistically significant as evidenced by chi square of 2.658 and p value of 0.617, the distribution of number of cases between two periods are uniformly increasing.

Due to awareness created by various Government programmes and advertisements by media persons there is good awareness among rural folks. This is evidenced in our study where the case detection was 75.2% in 2014-2015 in rural population when compared with the previous period of 53.8% in 2009-2010 in rural population. This clearly shows the statistical significance with respect to residence between two periods as evidenced by

chi square value of 52.960 and p value of 0.000. .Majority of the population were Hindus while Christians and Muslims were less in number .In our study there is no statistical significance between different religions with respect to two periods.

As the literacy rates have increased and as there is increased awareness among people even from rural population by various awareness campaigns conducted by the Government, there are more number of cases detected in the current period. Hence there is statistical significance with respect to education among two periods as evidenced by chi square of 77.684 and p value of 0.000.

Economic status of the women is assessed by their occupation and family income.In our study occupation and family income does not show any statistical significance between two periods.

There is a steep decrease in the early marriages in the current period when compared to previous period .This is because of increased literacy levels and more awareness among women in this current period .Hence age at marriage has statistical significance between two periods in our study as evidenced by chi square value of 537.292 and p value of 0.000.

In the current period ,parity upto 5 are 92.5% and in the previous period it is 73 % .Eventhough parity 1-5 is noticed in the present study most of them have 3-5 parity .This clearly shows that high parity women develop cancer cervix .There exist a statistical significance with respect to high parity between two periods in our study as evidenced by chi square of 75.323 and p value of 0.000.

There exist a statistical significance between age at first issue between two periods which is evidenced by chi square of 246.509 and p value of 0.000. Not a single case of age at first issue less than 17 years was detected in the present period whereas 30.9% of the total number of cases were detected in the previous period. There exist no statistical significance among two periods with respect to referral groups and this is evidenced by chi square value of 0.474 and p value of 0.491.

Per speculum alone as a method of screening is having a sensitivity lesser comparative with other screening methods .In present period only 5.8% patients were screened by per speculum .Eventhough the initial screening is by pap smear and VIA VILI ,confirmation is by colposcopy guided biopsy. There exist statistical significance with respect to colposcopic confirmation between two periods in our study..

There exist no statistical significance among two periods with respect to presenting symptoms, type of lesion between two periods.

There exist a statistical significance between two groups with respect to different stages as evidenced by chi square value of 34.271 and p value of 0.000. The detection of early stage cancers of the current period is 11.2% when compared to the previous period of 6%. Hence in the present period there is early detection and hence treatment could be started immediately and hence mortality could be reduced significantly in the present period.

Conclusion

CONCLUSION

Cancer cervix continues to be a major health problem in countries like India. This study is attempted to analyse the knowledge available regarding the epidemiology, various pattern of cervical cancer, and various risk factors.

In the current period, there is early detection of cases when compared to the previous period in women less than 35 years. The awareness among rural women has also increased due to the various government programmes and advertisements by media persons in the current period. Therefore the number of women detected among rural areas has been increased. As the literacy rates are increased in the current period as per educational statistics, the effectiveness of awareness programmes are also increased.

There is no statistical significance with respect to occupation and religion. The early age at marriage and age at first issue is an important risk factor for cancer cervix and this has been reduced in the current period. With the changes in the socio-economic profile, different screening strategies, easy accessibility of screening services and with increased awareness among women including women from rural areas with adequate literacy rate, there is an elevation of cancer cervix detection in the early

stage itself in the current period when compared to the previous period.

With early detection, patients could be treated effectively and the morbidity and mortality could be decreased.

Dear Dr.Kavitha.D.

The Institutional Ethics Committee has considered your request and approved your study titled **"COMPARATIVE STUDY OF DEMOGRAPHIC PROFILE OF PATIENTS WITH CANCER CERVIX ATTENDING IOG IN THE CURRENT PERIOD WITH THAT OF 5 YEARS AGO "** NO.08032015.

The following members of Ethics Committee were present in the meeting hold on 03.03.2015 conducted at Madras Medical College, Chennai 3

- | | |
|---|----------------------|
| 1. Prof.C.Rajendran, MD | :Chairperson |
| 2. Prof.R.Vimala,MD.,Dean,MMC,Ch-3 | : Deputy Chairperson |
| 3. Prof.B.Kalaiselvi,MD.,Vice Principal,MMC,Ch-3 | : Member Secretary |
| 4. Prof.R.Nandini,MD.,Inst.of Pharmacology,MMC | : Member |

INTRODUCTION

Cervical Cancer is an important cause of morbidity and mortality in women worldwide. In developing countries where healthcare resources are limited, the second frequent cause of cancer death in women is cancer cervix.

With appropriate diagnosis, treatment and follow-up, Cervical Cancer can be prevented and cured at low cost with the available screening for asymptomatic women.

The age distribution of the patients is bimodal with high incidence at 35 to 39 years and 60 to 64 years of age.

Carcinoma of the cervix is a multifactorial disease and main causative agent is Human Papilloma Virus. It is determined to be the main agent in the development of squamous and adenocarcinoma of the cervix. Of the 14 high risk HPV subtypes: 16 & 18 are found in 62 % of cervical cancer. The mechanism is through the interaction of the viral E6 and E7 proteins with tumour suppressor genes p53 and Rb. Inhibition of p53 prevents cell cycle arrests and cellular apoptosis, inhibition of Rb disrupts transcription factor E2f resulting in unrepleted cellular proliferation.
